

ABSTRACT

[0035] A quick-coupling device comprises a support (18) on which the female member (20) is mounted such that it can move between a position of retaining the male member (14E) in a position fitted into the female member (20) and a position of releasing the male member (14E) from the female member (20). This device also comprises a lever (24) articulated to the support (18) between a rest position, separated from the female member (20), and a position of collaboration with the female member (20), allowing this female member (20) to be driven toward its position in which it releases the male member (14E). As a preference, the lever (24) comprises means (26) for guiding the male member (14E), these being positioned on this lever (24) in such a way as to encourage guidance of the male member (14E) to mate it with the female member (20) when the lever (24) is in the rest position.
